Women’s Health App – Fitness Module PRD

Introduction and Background

The Women’s Health App is a holistic health platform with four primary modules: **Period Tracking**, **Pregnancy**, **Nutrition**, and **Fitness**. This PRD focuses on the **Fitness Module**, which is deeply integrated with the other modules to provide personalized workout guidance for women. The fitness module’s goal is to help users stay active and healthy through tailored exercise plans that consider their menstrual cycle or pregnancy stage, personal fitness goals, and overall health data.

This module will deliver a highly personalized fitness experience. It adapts workouts to where a woman is in her cycle or pregnancy and aligns with her goals (e.g. weight loss, strength building). It also encourages consistency and engagement through habit-forming features and integration with the app’s other health insights. **No platform constraints or premium limitations** are assumed – all users have full access to the described features on all platforms (iOS/Android).

Goals and Objectives

- **Personalized Workouts:** Provide daily workout recommendations and programs tailored to the user’s hormonal phase (menstrual cycle phase or pregnancy trimester) and fitness goals, making workouts more effective and relevant.

- **Integrated Health Experience:** Connect fitness with the Period, Pregnancy, and Nutrition modules. For example, adjust exercise intensity if the user is on her period or suggest nutrition tips that complement her fitness plan.

- **User Engagement and Retention:** Increase engagement through dynamic content, AI-driven tips, and gamification (streaks, badges). The module should help form healthy exercise habits and keep users coming back consistently.

- **Guidance and Education:** Offer an AI-powered virtual coach/chatbot and informative tips so users can get questions answered (e.g. “Is it safe to exercise during cramps?”) and learn proper exercise techniques, promoting confidence and safety.

- **Flexibility and Ease of Use:** Cater to different user preferences – whether they want a structured multi-week program or a quick daily workout – and allow users to adjust, skip,

or log workouts easily. Ensure the design is intuitive and the experience is enjoyable on any platform.

User Personas and Use Cases

While the app is for all women interested in health, the fitness module particularly serves:

- **Cycle-Tracking Users:** Women who track their menstrual cycle and want workouts aligned with their cycle phases. For example, a user in her luteal phase might get a lower-intensity workout recommendation, whereas follicular phase might have higher intensity.

- **Pregnant Users:** Expectant mothers using the pregnancy module who need safe, trimester-specific exercise routines (e.g. gentle stretches in third trimester). The fitness content dynamically adjusts for pregnancy stage.

User Journey Highlights: A typical journey might involve the user opening the app each day to see a **personalized fitness card** with that day's recommended workout. She might follow a guided **exercise session**, mark it complete, and see her calories burned and streak count. On other days, she might explore and start a new **multi-week program** (e.g. a 4-week strength training plan) or do a specific **one-off workout** (like a 15-minute abs routine). Throughout, she receives **AI tips** and can ask the **chatbot** questions. If she's also using Nutrition, she'll see a suggested healthy meal on her fitness screen (and vice versa) to cross-support her goals.

Scope and Assumptions

- **In Scope:** All features related to the fitness module's user-facing experience – personalized cards, workout content (programs, exercises), tracking, integrations with other modules, chatbot interactions related to fitness, and push notifications for fitness.

- **Extended:** Detailed development of the content (e.g. creating exercise videos/animations is handled by content team), complex AI algorithms in Phase 1 (some adaptive AI features may roll out in Phase 2, see AI Feedback Loop below), integration with third-party wearables (not at launch), and any premium/paywall considerations (all features are available to all users by assumption).

- **Assumptions:**

    - The backend provides the necessary data (exercise library, programs, user's cycle phase, etc.) and can handle dynamic plan generation based on rules (cycle phase, goals). The positioning of content cards on the screen is controlled via

backend for consistency across modules.

- No technical constraint on platforms: features like video playback, audio cues can be implemented using native capabilities (e.g. Chromecast on Android, AirPlay on iOS where possible).

- Users have provided basic info either during onboarding or later (age, height, weight, fitness goal, etc.) to personalize plans. If not, the app will prompt for necessary details at relevant moments (e.g. asking for a fitness goal when the user first uses the fitness module).

- The design language follows the overall app's style guide for a unified look across modules, but will incorporate unique visuals suitable for fitness (images of exercises, etc.).

Features and Requirements

1. Personalized Fitness Home Screen (Dynamic Main Card)

Each user will see a dynamic **main card** at the top of the Fitness home screen, which serves as the entry point for her daily recommended workout. This card is highly personalized:

- **Daily Workout Recommendation:** The card shows **today's workout** tailored to the user's context:

    - *Cycle Integration:* If the user is tracking her period, the workout aligns with her menstrual phase (e.g., a gentle yoga on period Day 1 vs. an intense HIIT during mid-cycle ovulation when energy is high). If the user is pregnant, it aligns with her current week/trimester of pregnancy (e.g., pelvic floor exercises in third trimester).

    - *Goal Alignment:* It also considers the user's fitness goal (e.g., weight loss, strength, general wellness) and preferences. For instance, a user whose goal is "Lose weight" might see a cardio-focused routine, whereas "Build muscle" might see a strength training routine. These goals are gathered from initial fitness onboarding or user profile.
    - ***Reminders:***On onboarding when first time opening fitness module and if user does not set it then asking after first workout and then any logic to ask user to set reminder for workout : Ask user to set the reminder for workout

- **Content of the Card:** The card displays an inviting summary of the workout:

    - A title or message conveying personalization (e.g., "**Energizing Cardio for Day 2 of Your Cycle**" or "**Prenatal Yoga – Week 20**").

    - A representative image for the workout. The image library will have category-based visuals so that the card image reflects the type of exercise (yoga, cardio, strength, etc.) or the context (pregnancy, menstrual phase) for variety. *For example, a yoga day might show a woman in a yoga pose, a cardio day might show a running silhouette.* The system will rotate through a set of relevant images to keep it fresh.

    - A brief descriptor or subtitle, e.g., "**15 min – Full Body Stretch**" or "**30 min – Strength & Tone**", indicating duration and focus.

    - **Call to Action (CTA):** A prominent "Start Workout" button (or similar wording) when the workout has not been started yet.

- **Dynamic State Changes:** The main card's appearance and text will change based on the user's progress state:

    - **Not Started (Planned):** Default state each day (or when a new plan is generated). Shows the workout summary and a **Start** CTA.

    - **In Progress:** If the user began the workout but hasn't completed it (e.g., left in middle), the card reflects this. For instance, it might show "In Progress: 2 of 5 exercises done" with a progress bar or partial ring. The CTA might change to "Resume Workout". This state reminds the user to continue where she left off.

    - **Completed:** Once the user finishes the recommended workout, the card updates to celebrate completion. It could display a message like "✅ Workout Complete!" and show **calories burned** (e.g., "You burned 120 kcal today!") and perhaps an encouragement ("Great job!"). The card might turn a different accent color or show a trophy icon to reinforce the achievement. No primary CTA in this state, though a secondary action could be "View History" or "Share" if applicable (backend for now)

- **Forward Planning:** The user can swipe or tap to see the **upcoming days' plan** (e.g., see the next 7 days of workouts in advance). The system generates a week-long schedule that is adaptive (if the user's cycle phase will change mid-week, the plan reflects that). This allows users to preview and mentally prepare for upcoming workouts. However, only the current day is the actionable card at a time. Keep the number of days to see the plan configurable.

- **Plan Regeneration & Updates:** Each week (or after the last planned day), a new plan is generated taking into account any new data:
    - If the user edited her period dates or became pregnant, the plan updates immediately to stay in sync with her current status.
    - If the user changed her fitness goal or indicated new preferences, subsequent recommendations adjust accordingly.
- **Logging Integration:** The main card is tied to the user's workout log:
    - If the user skips a day (does not complete the planned workout on that day), the plan simply moves on to the next day's workout; the missed workout could be recorded as missed (for internal analytics or AI feedback) but not shown as a backlog to the user to avoid overwhelming them.
    - The user may choose to do a different workout than the one recommended (e.g., she ignores the main card and does a separate program workout). In this case, the main card's workout remains available if she wants to do it later that day, but if the day passes without doing it, it's just missed. Our focus is on encouraging but not forcing the daily suggestion.
- **Rationale:** This personalized card aims to make the app feel like a **personal trainer** who knows the user's situation. By acknowledging things like "You are in your luteal phase" or "Second Trimester" and adjusting workout type accordingly, we increase relevance. This boosts user trust and likelihood to follow the plan. *(This approach aligns with emerging apps like Wild.AI that tailor guidance to women's hormonal phases.)* It also differentiates us from generic fitness apps by leveraging our integrated women's health data.

2. Daily Fitness Plan ("Daily Habit" Recommendations)

In addition to the main personalized workout, the module will offer a **Daily Fitness Plan** feature – essentially quick standalone sessions that act as daily habits or challenges:

- **Daily Mini-Workout:** Each day, users can access a short-duration exercise routine (e.g., a 5-10 minute workout) highlighted as a daily challenge. These might be labeled as "Daily Fit Habit" or similar. Examples: "7-Min Morning Stretch", "5-Minute Abs Blast", "10-Min Mindful Breathing & Stretch".
- **Changing Daily:** The content of this daily plan changes every day, providing variety and touching on different fitness aspects throughout the week (flexibility, core strength, cardio burst, etc.). These are generally not tied to a multi-week progression – each day's

mini-workout is self-contained.

- **Integration with Main Plan:** If a user is already doing a structured program or the main daily recommended workout, this feature serves as a bonus or alternative. It's not required, but it's a way to keep light activity going on rest days or for users who aren't up for a full workout. For example, if the main card suggests a 30-minute workout but the user is short on time, she might do the 7-minute routine instead.

- **UI Presentation:** On the Fitness home, below the main card (and AI tips – see next feature), there will be a section for "**Today's Mini Challenge**" or "**Daily Quick Workout**." It will show one highlighted mini-workout with its title and duration. Possibly, an option to "See All" to view the upcoming or past daily challenges for the week (though since they change daily and are short, we may just keep it one-at-a-time without backward browsing).

- **Completion Tracking:** Similar to the main card, if the user completes the daily mini-workout, it shows as completed (a checkmark or "Done" label). If incomplete, it just expires end of day. There's no ongoing "program" to track here – it's meant as a one-off daily suggestion.

- **Notification Tie-in:** We can use this feature to send a fun push notification each day: e.g., "Your 5-min daily workout is ready: Time to stretch out!" to gently nudge the user to open the app and do it.

- **Purpose:** This feature lowers the barrier to exercise by providing something that requires minimal time and no commitment. It helps users build consistency. Even on busy days, a user can at least do the Daily Habit workout to keep her streak. This supports habit formation (small wins) which is known to encourage regular app use.

3. AI Tips and Insights (Contextual Guidance)

Across the app (including the fitness module), we have a concept of **AI Tips** – small nuggets of personalized insight or suggested questions that appear in the feed. In the fitness module:

- **AI-Powered Tip Cards:** Directly underneath the main workout card, the user will see a few short tips or questions each day. These are tailored to her current context and data. For example:

    - "Feeling sore? Ask how to speed up muscle recovery."

    - "Hydration affects your workout – learn more."

    - “You’re on Day 2 of your period. Find out how exercise can ease cramps.”
    - These appear as a sentence or question on a card, possibly with a small icon (like a chat bubble or lightbulb).

- **User Interaction – Chatbot Launch:** When the user taps one of these tips/questions, it will **launch the AI Chatbot** interface (see the Chatbot feature below for details). The selected tip/question is passed as the first query to the chatbot. The AI then provides a helpful answer or advice in a conversational format.
    - Example: The user taps “How can I reduce period cramps with exercise?” – the chatbot opens and answers with a few suggested exercises or stretches that alleviate cramps, and the user can continue to ask follow-ups.

- **Source of Tips:** These tips/questions can be generated or curated by the backend’s AI or content team. They will be context-sensitive:
    - Period context: If user is in a certain phase or logged a symptom like “cramps” or “low energy”, tips will reflect that (e.g., tips about gentle workouts or nutrition during PMS).
    - Pregnancy context: If user is pregnant, tips might include prenatal exercise safety, or questions like “Is it safe to do squats in 2nd trimester?”.
    - Fitness behavior: If the user has been consistent or inconsistent, tips could adapt (e.g., after a week of workouts, a tip might be “Why rest days are important” or if user hasn’t been active: “How to get motivated when you fall off track”).
    - General wellness: Tips about form, hydration, sleep and recovery, etc., relevant to all users.

- **Frequency:** We will show up to 3 AI tips per day in the fitness feed (similar to how other modules do). If we have fewer relevant ones, we can show 1-2. These refresh daily, so each day there’s something new to learn or ask.

- **Benefit:** This feature turns passive data into active guidance. It provides educational value and drives engagement by inviting the user to interact (ask questions). It leverages AI to give on-demand advice in a scalable way. By addressing users’ likely questions (that they might not even have thought to ask), we increase the perceived value of the app as a knowledgeable companion.

- **Design:** These tips will be styled distinctly (perhaps smaller cards or different color) so they’re noticeable but not confused with actionable workout items. They basically act as

prompts to open a chat. They should be concise and intriguing to maximize taps.

4. Multi-Week Fitness Programs ("Your Programs")

Many users benefit from a structured routine over several weeks. The Fitness Module offers **Programs** – curated multi-week workout plans targeting specific goals or themes.

Key aspects of Programs:

- **Program Library & Categories:** The app will have a library of programs designed by our fitness experts. Examples:
    - **General Fitness & Wellness (4 weeks)** – a balanced program combining cardio, strength, and flexibility.
    - **Lose Weight – HIIT Cardio (6 weeks)**.
    - **Strength Training for Beginners (8 weeks)**.
    - **Prenatal Fitness – 1st Trimester (4 weeks)**, **2nd Trimester**, etc., adjusting intensity for each stage.
    - **Postpartum Recovery Program (X weeks)** – safe exercises after childbirth.
    - **Targeted Programs:** e.g., "30-Day Abs Challenge", "Glute Toning 4-week Program" etc.
- **"Your Programs" Section on Home:** On the fitness home screen, below the daily sections, there will be a **"Your Programs"** card or carousel. This highlights the user's active program(s) or recommended programs:
    - If the user has already started one or more programs, those appear here with progress status. (We may limit to highlighting one active program at a time – typically users focus on one program. But if they have multiple in progress, we could let them scroll through their active ones.)
    - If the user has no active program, this section will recommend a program based on her goal and profile (e.g., "Kickstart your fitness: Try the 4-week Wellness Program!"). Possibly two or three recommendations could be shown, or just one with a "See More".
    - A **"See All Programs"** link or button leads to the full Programs library page with filtering options.

- **Programs List Page:** When the user taps to see all programs, she is taken to a **Programs Library** screen:
    - Programs are listed with a thumbnail image, name, brief description (e.g., duration, difficulty, goal).
    - The user can select one program from the list and can select another once they complete the current program.

- **Program Detail Page:** Selecting a specific program shows its detail:
    - **Overview:** Top of the page shows program title, a cover image, difficulty, duration (e.g., 4 Weeks), and possibly estimated time per day (e.g., "~30 min/day, 5 days/week"). Also a short description of what the program focuses on.
    - **Week Breakdown:** The program is organized by weeks and days:
        - We will list Weeks (Week 1, Week 2, …) and under each, the days of that week. Since the program doesn't know the user's start date initially, days can be numbered generically (Day 1, Day 2, … Day 7) for each week.
        - Alternatively, the UI might just list Day 1 through Day N (e.g., Day 1 to Day 28 for a 4-week program) grouped by weeks.
        - If the user **has not started** the program yet, days are just labeled by number. Once the user **starts** (say she starts on a Wednesday), the app could optionally display actual dates or weekdays for each day to help schedule (e.g., Day 1 – Wed Oct 5, Day 2 – Thu Oct 6, etc.). This is a nice-to-have feature; if complex, we can keep it as Day 1, Day 2, etc., and rely on the user to do one per day.
    - **Daily Workout Items:** For each day in the program, list the exercises or routine for that day. Likely this appears when you tap on a day:
        - A list of exercises with their names, reps/sets or duration (e.g., "Squats – 3 sets of 15; Push-ups – 2 sets of 10; 10-minute jog…" etc.). Possibly with small thumbnail icons or an expand arrow.
        - If a day is a rest day (some programs schedule rest), it will indicate "Rest Day".
    - **Start/Resume:** If the user has not started the program, there will be a CTA "Start Program" (which typically means begin Day 1 immediately or mark the program as active). If the user already started and is partway through, the CTA might say

"Continue – Day X".

- **Bookmark:** A **Save/Bookmark** icon (like a ⭐ or bookmark ribbon) allows the user to save the program to their list without starting it. This is useful if she likes the program but wants to do it later. (Saved programs can be filtered or shown under a "Saved" list possibly).

- **State and Progress:** The program detail should clearly show progress if started:

  - Completed days are marked (checkmark or colored differently).

  - The current day is highlighted.

  - Perhaps a progress percentage or fraction (e.g., "Day 8 of 28 completed").

  - If the user pauses/doesn't do a day, the program just waits; there is no strict enforcement of schedule, but we will encourage one per day.

- **Executing a Program Day:** When the user selects a day (today's or any pending day) from the program detail and hits start:

  - It launches the **Exercise Session flow** (described in a later section) for that day's sequence of exercises.

  - Upon completing the session, that day is marked complete in the program, and the next day becomes available.

  - The user can only move sequentially (cannot jump ahead to later days without completing prior days, unless she explicitly chooses to skip them).

  - If a user misses days, she can resume where left off; the program doesn't auto-expire. (We might consider sending a reminder if she hasn't done her program workout in a while.)

- **Dynamic Adjustments:** Programs themselves are mostly fixed content, but the selection of recommended programs is dynamic:

  - If the user is pregnant, the program list shown will prioritize pregnancy-safe programs (or even hide non-applicable ones).

  - If the user's goal is weight loss, we might highlight cardio/HIIT programs in recommendations. Similarly, for muscle gain, highlight strength programs.

    - The app could even automatically assign a default program during onboarding (e.g., after user answers goal and level, say “We recommend the Beginner Full-Body Fitness 4-week plan to start”). The user can accept or choose another.

- **Why Programs:** Programs provide long-term guidance and a sense of progression. They help users commit to a routine and see improvement over weeks. By showing progress (weeks/days completed), it taps into the user’s motivation to finish what they started. It also adds content depth to the app. We know that without long-term engagement features like clear goals or progress tracking, users lose interest. Structured programs address that by giving the user a roadmap and a goal to work towards (completion of the program).

6. Exercise Session Flow (Guided Workout Player)

This is the core experience when the user is actively doing an exercise or routine. Whether the user starts the daily recommended workout, a program day, or a single workout, the **workout player** guides them through exercises. Key requirements:

- **Exercise Instructions & Media:** For each exercise in the routine, the app will display:
    - The name of the exercise (e.g., “Squats”).
    - A visual demonstration: ideally an **animation or video** clip showing the correct form. These could be preloaded short looping videos or high-quality GIFs for each exercise. If equipment is needed (e.g., dumbbells, yoga mat), the video should show that or we textually indicate it.
    - Text instructions or tips (if user taps an info icon or if we always show a short tip like “Keep your back straight”).
- **Sequence Navigation:** The session includes multiple exercises in sequence:
    - The UI will show a progress indicator (e.g., “Exercise 3 of 10”) and perhaps a timeline or dots for each exercise.
    - **Next/Previous:** User can tap “Next” to move to the next exercise (or it auto-advances after a set time if it’s time-based).
    - If an exercise has multiple sets, the app might prompt the user for each set (e.g., “Set 1: 15 reps – tap Next when done” then “Rest 30 seconds” then “Set 2: 15 reps”, etc.). Alternatively, we list “3 sets” and the user just does them and taps next after finishing all.

- **User Controls:**
    - **Pause/Resume:** The user can pause the workout at any time (which might dim the screen and pause any timers).
    - **Adjusting Reps/Sets:** For more interactivity, we allow the user to **log what they actually did**:
        - If an exercise called for 2 sets but the user feels good and does 3, she can add a set in the interface (a "+" button to record an extra set).
        - If an exercise was too hard and she did fewer reps, she might be able to adjust the count (or she could simply move on).
        - If an exercise is time-based (e.g., 30 seconds plank), perhaps a toggle to mark if she extended to 1 min (though this might be rare; more likely we stick to reps/sets adjustments).
        - These adjustments will recalc the calorie estimate accordingly in real-time or at the end. (Increasing sets or reps increases calories burned).
    - **Skip Exercise:** The user can choose to skip an exercise if she cannot or doesn't want to do it. We should allow skipping and mark that exercise as skipped (and perhaps prompt for feedback like "Why skip?" for our data, though not required).
    - **Exit Workout:** If the user decides to stop the session entirely mid-way, she can exit. In this case, if she's in a program/day context, we might treat the day as incomplete. On exit, show a confirmation "You haven't finished the workout. Are you sure you want to quit?" If confirmed, we save progress (e.g., 5/10 exercises done) as an **In-Progress** status.
- **Voice and Audio Feedback:**
    - At the session start, play a brief **voice prompt** like "Let's begin your workout!" or a countdown "Workout starting in 3…2…1".
    - For each exercise, optionally have a voice say the name or give a cue ("Next: Squats for 15 reps"). This can help users who aren't looking directly at the screen.
    - Background music: Provide an optional simple background beat or music track during the session to keep energy up. If not feasible to sync to exercises, at least a consistent light music. Alternatively, allow the user to play their own music

externally; ensure our app's audio doesn't conflict.

    - The user can mute/unmute voice or music as needed (icons for volume).

- **Casting to TV: (optional)**

    - Include a **Cast icon** on the workout player screen. When tapped, it triggers casting of the workout content to a smart TV or Chromecast-enabled device. This way, the user can follow the workout on a large screen.

    - Use native casting frameworks (Google Cast, DLNA, etc. on Android; AirPlay on iOS if possible). Once connected, show a "Casting…" status and allow control from the phone as a remote (next/pause etc.).

    - If casting is active, the phone screen can show minimal controls while the TV shows the main video. Ensure to test both platforms. (Casting is a common expectation for fitness apps so users can exercise hands-free viewing.)

- **Info/Instructions Pop-up:**

    - Provide an **Info (ℹ️) button** or "How to" on each exercise screen. If tapped, it pauses the session and shows detailed instructions, tips, or modifications for that exercise:

        - For example: "Squats: Stand with feet shoulder-width apart, back straight. Bend knees to 90°, keeping knees behind toes, then rise. Tip: Engage your core. Modification: Use a chair for support if needed."

    - This helps users ensure proper form and reduce injury risk, especially beginners unfamiliar with moves.

- **Progress Tracking During Session:**

    - A small counter might show real-time **calories burned so far** in the session (based on MET values, user weight, and completed exercises). This is encouraging as it climbs.

    - If the workout is time-structured, show a timer for that exercise or total session time.

    - If applicable, show heart rate if connected to a device (likely not in initial scope, but maybe future via Apple Health/Garmin integration).

- **Completion and Results:**
    - When the user finishes all exercises and hits the final **"Done"** button, show a **completion summary** screen:
        - Congratulatory message ("Workout Complete! 🎉").
        - Total calories burned in this session.
        - Perhaps total duration or steps/reps done.
        - If this completes a program day or daily goal, mention it ("Day 5 of 28 completed" or "You kept your streak going!").
        - Encourage hydration or cooldown ("Don't forget to stretch and hydrate.").
        - Offer a button to return to Fitness home or to share the achievement (maybe share on social media that she finished a workout, if appropriate).
    - This completion screen is important for positive reinforcement – an "aha moment" that rewards the user's effort. It motivates future workouts. *We will integrate a calorie summary here as that concrete feedback (e.g., "You burned 200 kcal today") is very satisfying to users and gives a sense of accomplishment.*
- **Interruption Handling:**
    - If the app is backgrounded or a call comes in, the session should pause automatically. On returning, user can resume.
    - If the app crashes or device reboots mid-session, at least mark the session as incomplete so the user can start over or mark as done manually.

9. Cross-Module Integration (Period, Pregnancy, Nutrition)

One of the Fitness Module's greatest strengths is its integration with the other modules in the Women's Health App. This ensures a **holistic user experience**:

- **Adaptive to Menstrual Cycle:**
    - The fitness content (daily workout, programs suggestions) adapts based on the user's menstrual cycle data from the Period module:
        - During menstruation days, emphasize lighter exercises, yoga, or stretching that can help with cramps and fatigue. Possibly label them as

"Period-friendly workout".

        - During follicular phase (post-period to ovulation), energy levels tend to be higher – app can schedule more intense workouts (cardio, strength).
        - Around ovulation, some women feel strong; high-intensity or PR (personal record) attempts can be placed here.
        - Luteal phase (pre-period) often comes with lower energy or PMS symptoms, so moderate the intensity and include mood-boosting exercises.
    - The app should dynamically adjust if the user's period start date shifts. For example, if her period comes early, the upcoming workouts for that week should recalibrate to lighter intensity on those new period days.
    - By doing this, we personalize on a level beyond typical fitness apps, acknowledging women's physiological variations. *(This concept is validated by apps like Wild.AI focusing on phase-based training.)*

- **Adaptive to Pregnancy:**
    - If the user is in Pregnancy mode (the app knows she's pregnant and her current week):
        - Only safe exercises and programs are recommended. The main daily workout will be something like "Prenatal workout – Week 20" with exercises vetted for that stage (no lying flat on back after first trimester, etc.).
        - Programs offered will be pregnancy-specific (trimester-wise programs for prenatal fitness, or perhaps a walking program, etc.).
        - Workouts that are not safe (like high-impact HIIT or certain abdominal exercises) will be filtered out entirely during pregnancy.
        - As the user progresses in pregnancy, the recommendations automatically update. For example, entering third trimester might shift focus to gentle stretching, breathing exercises, and light strength for labor preparation.
        - If the user has the baby (ends pregnancy in app), the app will switch back to period mode postpartum and possibly suggest postpartum recovery exercises.

- **Nutrition Upsell and Integration:**
    - The fitness module will subtly encourage the user to leverage the Nutrition module, since diet and exercise go hand-in-hand for health:
        - On the Fitness home, there will be a card or section like **"Today's Nutrition Tip"** or **"Suggested Meal"**. This could show a recipe or meal from the Nutrition module.
            - If the user **already has a nutrition plan** active, we fetch one of her planned meals for the day (e.g., her lunch or a snack) to display. For example: "Grilled Chicken Salad – 350 kcal" with maybe a picture, to remind her of her nutrition plan.
            - If the user has **not set up nutrition**, we show a generic healthy recipe or tip, possibly related to her fitness goal or phase. E.g., "Protein Smoothie for Recovery" or "Iron-rich foods to eat during your period." When she taps it, we then prompt to set up the nutrition module.
        - Tapping the nutrition card will lead the user into the Nutrition module:
            - If not set up, it may first ask a few quick questions (dietary preferences, goal) to personalize, then show the full recipe or plan. We'll ensure the transition is smooth and not jarring (possibly via a modal asking "Would you like personalized meal plans? Let's get your preferences").
            - If already set, it goes straight to the recipe details or nutrition dashboard (contextually).
    - Conversely, in the Nutrition module's UI, a fitness teaser can appear. E.g., on a day the user logs high calories, Nutrition might show "Burn extra calories with a quick workout – try this 10-min HIIT". Tapping it takes them to the Fitness module.
    - This cross-promotion increases usage of both modules and helps the user see better results (since fitness + nutrition together are more effective). It's an upsell but also a logical connection for a holistic health approach.
- **Combined Dashboard and Logging:**

    - The app's main dashboard (overview screen) will incorporate fitness data along with period and nutrition:
        - For instance, on the main screen, it might greet "Good Evening, [Name]. You have a workout planned and 2 meals logged today." or show key highlights from each module.
        - If the user hasn't engaged with the fitness module yet, the main dashboard might show a card like "Try a period-friendly workout today!" as an entry point to fitness.
    - A **Global Add ("+") Button** will allow quick logging or actions for any module. For fitness, if a user taps "+", one option would be "Log Exercise". This is primarily if the user did some physical activity outside of the guided workouts (e.g., went for a 5km run, or a gym class). She can input that manually:
        - Enter type of activity, duration, intensity, and the app estimates calories.
        - This gets added to her fitness history and counts towards streaks.
        - This ensures users can keep all their activity recorded, not just the in-app guided sessions.

- **Notifications across modules:**
    - The app will avoid redundant or conflicting notifications. If a user is active on fitness, a nutrition reminder might be timed differently.
    - We may have a **smart notification scheduler** that prioritizes what to remind based on user's primary focus. E.g., if user consistently does workouts at 7am, we'll send the fitness reminder then, and maybe a nutrition one at lunchtime, etc.
    - Some notifications combine info: "Great workout today! Log your post-workout snack in Nutrition to refuel."

10. AI Chatbot (Virtual Coach Assistant)

The Women's Health App includes an **AI-powered chatbot** that serves as a virtual coach or assistant across modules, including fitness. For the scope of fitness module:

- **Functionality:** The chatbot provides on-demand answers, coaching, and support to user queries or prompts, leveraging AI (e.g. a Large Language Model tuned for health & fitness advice) and context from the user's data.

- **Entry Points:**
    - Tapping the **AI Tips , Stories , Health Alerts** as described earlie , will open the chatbot with that question pre-loaded.
    - A **“Chat” or “Ask” button** might be persistently available on the screen (e.g., a chat icon). For instance, “Ask AI” where users can freely ask a question about health.
    - A **Health Check-Up** feature: The user might see a card “Health Checker” on the main dashboard. If she taps it, it could be a chatbot-driven interactive quiz (like asking about symptoms or mood and giving tailored advice).
- **Context Awareness:** The chatbot will have access (with user permission) to some of the user’s context:
    - It knows if the user is on her period or pregnant, and which week.
    - It knows the user’s recent fitness activity (“I see you did cardio yesterday”).
    - It knows her goals and maybe struggles (if gleaned from history, e.g., she often skips workouts on Mondays).
    - Using this, it can personalize responses. E.g., “Because you’re in your luteal phase, you might feel a bit low energy. It’s okay to take it easy – maybe do some yoga which can also ease PMS symptoms.”
- **Example Queries the Chatbot Can Handle:**
    - User asks, “I have knee pain, what exercises should I avoid?” – The chatbot can respond with caution about high-impact moves and suggest alternatives or advise seeing a doctor if severe.
    - User asks, “Can I do abs workouts during pregnancy?” – The bot responds with trimester-specific guidance (e.g., avoid certain positions after first trimester, suggests safe core exercises).
    - After completing a workout, the user says “That was tough, any tips to improve my push-ups?” – Bot gives training tips for push-ups.
    - Nutrition-related from fitness context: “What should I eat after a workout?” – Bot can give a quick recommendation for protein/carb intake.

- **AI Source and Safety:** The chatbot will be powered by a reliable AI model with a knowledge base of fitness and health guidelines. It should cite credible sources if giving medical advice and include disclaimers for any sensitive topic ("This is not medical advice, for concerns consult a professional"). We will also use our internal database of approved responses for common questions to ensure accuracy.

- **Phase 1 vs Future:** Initially, the chatbot might be somewhat scripted or limited to certain triggers (like the AI Tips we push). The **Phase 1** approach could be: we supply predefined question prompts and use an AI API to get answers on tap. In a **Phase 2**, this can evolve to a fully conversational agent that users can chat with freely at any time, with memory of the conversation.

- **UI/UX:** The chatbot interface will be a familiar messaging-style screen:

    - The AI messages appear with an assistant avatar (perhaps a friendly coach character or just the app's logo).

    - The user can type or voice-input questions.

    - We may include suggested follow-up questions or quick reply buttons to guide the conversation.

    - Option to end chat or clear context.

    - Possibly, the chat could hand off to different expert modes (nutritionist, fitness coach, gynecologist persona) based on query, but that might be behind-the-scenes logic rather than user-facing distinction.

- **Benefits:** This feature greatly enhances user support and education. Instead of the user having to google questions or leave the app, she can get trustworthy answers immediately. It's like having a coach or health expert available 24/7. This can also handle nuanced situations and provide personalization at scale (something static content cannot do). As noted in industry analysis, modern users expect more than basic tracking; they want coaching and guidance – the chatbot helps fulfill that expectation with AI's help.

11. Notifications & Reminders

To keep users engaged and on track, the fitness module will leverage push notifications (as well as in-app notifications/banners where appropriate):

- **Daily Workout Reminder:** If the user has a daily workout (from the main card plan or a program day) and hasn't completed it by a certain optimal time, send a reminder. This could be user-customizable (e.g., user sets "remind me at 7am every day" or we learn

she often works out in evenings and time it accordingly).

- Example: " 🏃 Ready for today's workout? Let's crush your goals!" or a more context-specific one: "It's Day 3 of your program – let's keep the momentum going!"

User Journey Example

To illustrate how these features come together, below is a **sample user journey** for a new user, "Alice," using the fitness module:

Onboarding & Personalization:

1. Alice downloads the Women's Health App and sets up her profile. She indicates her period cycle info and that her goal is to **"Lose weight and tone up."** She is not pregnant, so the app is in Period mode.

2. During onboarding (or first time visiting the Fitness tab), Alice answers a few quick questions about fitness: her current activity level (Beginner), and confirms her goal. The app uses this to tailor recommendations.

Day 1 – Discovering the Fitness Module:
3. Alice navigates to the **Fitness module**. The top of the screen shows a **Personalized Main Card**: *"Welcome Alice! Today's Workout: Beginner Full-Body Burn."* It notes it's a 20-minute session and appropriate for her phase (e.g., she's mid-cycle, so it's a standard workout).
4. She also sees an **AI Tip** below it: *"Why exercise is easier in your follicular phase – ask AI."* Curious, she taps it. This opens the **AI Chatbot** which explains how estrogen levels might be boosting her energy now and how to take advantage of it, citing some tips. She finds this interesting and closes the chat to start her workout.
5. Alice taps **"Start Workout"** on the main card. The app enters the **Exercise Session flow**. First, a friendly voice says "Let's start! Get ready for jumping jacks. Starting in 3…2…1…". Alice follows along with the animated demo.
6. As she progresses, a counter shows **"Exercise 3 of 8"**. She pauses on the 5th exercise (push-ups) to tap the info icon – a tip suggests doing them on knees if full push-ups are too hard. She does that modification and continues.
7. Partway, Alice's friend calls her, interrupting the workout. She exits the session after 5 of 8 exercises. The app prompts "Do you want to quit this workout?" and she confirms, as she plans to redo it later properly. The session closes.
8. Back on the Fitness home, the main card now indicates **"In Progress – 5/8 exercises done"** with a "Resume" button. Alice's schedule got busy, so she doesn't resume that day.

Day 2 – Resuming and Exploring Programs:
9. Next morning, Alice gets a **notification**: "Yesterday's workout is still incomplete. You got this!

Pick up where you left off." She clicks it and the app opens to the fitness module.
10. She hits **"Resume Workout"** on the main card and completes the remaining exercises. At the end, she sees a **completion screen**: "Congrats! Workout Complete – You burned 150 calories. 🎉" She feels accomplished.
11. The main card now shows **"Completed – 150 kcal burned"** for today (with a green check icon).
12. Scrolling down, Alice sees the **"Your Programs"** section. It highlights *"Beginner's Fat Loss – 4 Week Program"* as recommended for her. She taps it to learn more.
13. On the Program detail, she sees Week 1 through Week 4 breakdown, each day's workout list, etc. It's beginner level and fits her goal. She taps **"Start Program."**
14. A prompt asks if she wants to start now (Day 1 today). She accepts. Day 1 of the program is similar to what she just did, but she already exercised today. So she decides to do Day 1 tomorrow. The app marks the program as started.
15. She bookmarks another program ("Summer Yoga Challenge") for later, by tapping the ⭐ on that detail page.

Day 3 – Program Engagement and Nutrition Integration:
16. The next day, the main card now reflects her program: "**Week 1 Day 1: Full Body Basics**" since she started the program. She starts the workout and completes it fully.
17. After finishing, the card shows she completed Day 1 and burned X calories. She also earns a **badge: "First Workout in Program – Way to Go!"** with a small celebration animation.
18. Underneath, the app shows a **Nutrition suggestion card**: "Post-workout Meal: Try a Greek Yogurt Parfait for recovery." She taps it, which takes her to the Nutrition module. Since she hadn't set up nutrition, it asks a couple of questions (diet preference) and then shows the recipe. She likes it and logs it as her breakfast.

Subsequent Days – Building Habit:
21. Alice continues following the 4-week program. The app sends subtle reminders each morning. On Week 2, she hits a low-energy day (her period starts).
22. On that day, the app adapts: the main card says "**Period Day 1 – Gentle Yoga**" as her workout (the program schedules might allow a swap or a rest day which we replaced with a gentle session knowing her condition). It also shows an AI Tip: "Feeling cramps? Ask for stretching tips." She asks the chatbot and uses the advice given.
23. After her period, the program resumes with normal intensity. Alice notices the images on the main card change with each workout type, which keeps things visually interesting.
24. If she ever misses a day, the app doesn't scold – it simply adjusts. For instance, she skipped Day 5 of Week 2; the next day, the program still offers Day 5 (not done yet) to complete.
25. By end of Week 4, she finishes the program! She's greeted with a special **"Program Completed!"** badge/trophy on screen, summarizing her achievements (total workouts, total calories over 4 weeks, etc.). The app congratulates her on this accomplishment.
27. The "Your Programs" section now moves that program to "Completed Programs" list and perhaps suggests a next program (maybe Intermediate level now).

Social and Long-term:
29. She continues to use the app, switching between modules seamlessly: logging her period, following nutrition plans, and keeping up with fitness. The integrated experience makes it easy – her one app covers it all.

Through this journey, we see Alice benefiting from the personalized, adaptive and comprehensive features of the fitness module. The app met her where she was each day (energy high or low, schedule free or busy) and kept her engaged with a mix of structure (program), flexibility (one-off workouts), and support (AI tips, notifications, badges). This is exactly the outcome we aim for: **improved user satisfaction, retention, and health outcomes**.

Design and UX Considerations

While this PRD is primarily about functionality, certain design principles must be considered to make these features effective and user-friendly:

- **Consistent Card Layout:** The app uses a card-based layout across modules. The fitness module's main card and subsequent sections should visually align with this style for a unified feel. Headings, font styles, and spacing should mirror those used in Period, Pregnancy, Nutrition for familiarity.

- **Visual Appeal & Imagery:** Fitness content is highly visual. We will use:

    - Meaningful images on cards (as discussed for the main card and program thumbnails). Ensure we have a diverse set of images representing different exercises and body types, focusing on women to resonate with our users.

    - Possibly color-code or accent different workout types (e.g., cardio days have a blue tint image, yoga days green, etc.) – but subtle, so it doesn't clash with dynamic content.

    - Use icons to represent concepts: e.g., a flame icon for calories, a dumbbell for strength workouts, a mat for yoga, etc., alongside text labels.

- **State Indication:** Use clear visual indicators for statuses:

    - In-progress items might have a half-filled progress ring or a pause icon.

    - Completed items have checkmarks or dimmed appearance with a "Completed" label.

    - This applies to the main card, program days, and any list of workouts.

- **Interactive Feedback:** Buttons and taps should give immediate feedback (highlight, press effect). When a workout is marked done, instantly reflect it to reinforce the action (e.g., the card flips or changes color).

- **Navigation and Hierarchy:** The user should not feel lost given the depth of content.

    - Ensure a clear way to return to Fitness home from deeper pages (program detail, etc.) perhaps via a back button or tab navigation if Fitness is a tab.

    - Within program detail, allow easy jumping between weeks or days (maybe an accordion or swipe between weeks).

    - The “See All Programs/Workouts” should be easily discoverable (likely a button on the “Your Programs” card or a bottom nav item).

- **Performance:** Workout media (animations/videos) should be optimized for mobile. Use lower-resolution or vector animations to keep file size small for quick loading. Perhaps download them on the fly or in advance for the day’s workout. Avoid long buffering times which could frustrate users ready to exercise.

- **Accessibility:**

    - All actionable elements should be sufficiently large and accessible (important for users who might be tapping with sweaty hands mid-workout!).

    - Ensure color contrasts are high for text over images.

    - Provide text alternatives for audio cues (closed captions or on-screen text for those who mute sound).

    - Possibly integrate vibration feedback for countdowns (a short vibration at “go” if sound is off).

- **Error Handling:** If content fails to load (say a video doesn’t play), have a fallback: e.g., display the text instructions so the user can still proceed.

    - If the AI chatbot fails to get a response (network issues), show a friendly message and suggest trying again.

- **Design for Motivation:** Little design touches can boost motivation:

    - Animations when completing goals (confetti, progress bars filling up).

    - A friendly tone in copy (“You did it!”, “Keep going, you’re doing great”).
    - Perhaps an avatar or character that occasionally pops up with encouragement in the UI (optional fun element).
- **Privacy and Comfort:** Recognize that users might be self-conscious about certain data:
    - The app should never display weight or body metrics on the main UI in a way that others could glimpse if the user is working out in public. Keep sensitive data within profile or settings.
    - Also, ensure any community sharing is opt-in; the default is private usage.
- **Testing with Real Users:** Given the complexity, we should do usability testing with a few target users:
    - Ensure they understand how to start a program vs a single workout.
    - See if they notice the AI tips and find them useful.
    - Check that they don’t feel overwhelmed by too much content on one screen. We may need to balance how much to show on the home feed (perhaps collapsible sections or a clean scroll).
- **Design Deliverables:** We will need high-fidelity mockups for:
    - Fitness home screen (with examples of various states: no program vs with active program, before vs after workout, etc.).
    - Program list and detail pages.
    - Workout player screens (including casting state, info pop-up, etc.).
    - Insights/stats screens (charts, calendar, badges).
    - Chatbot interface (consistent with app theme).
    - Notification templates (for marketing team to follow tone).
    - These should follow our brand guidelines (color palette, typography). We might use energetic colors to motivate (our brand red/pink for active states, etc.).

- **Animation & Transitions:** Smooth transitions between states will make the experience polished. For example:
    - When hitting “Start Workout”, perhaps animate the card expanding into the full-screen player.
    - When completing, animate the stats appearing (e.g., number rolling up to the calorie count).
    - Streak counter could subtly pulse or animate when incremented.
- **No Platform Divergence:** Ensure the experience is equally good on Android and iOS. Use platform-native patterns appropriately (Material Design on Android vs iOS style where needed), but the core layout remains the same. If any feature (like casting) differs in implementation, hide those differences from the user (just make sure the icon works on both).
- **Scalability:** The design should accommodate localization (longer text in other languages), possibly different units (if we ever allow switching to kJ or something), and adding more content in future (like more modules or community features, etc.).

In summary, the design should be intuitive, motivating, and cohesive with the rest of the app. We want users to *enjoy* using the fitness module—finding it not only useful but also engaging and even fun. A well-thought-out UI/UX will reduce drop-offs and make it more likely that users stick with their fitness journey.

Metrics and Success Criteria

(To ensure the PRD is complete, we outline how we will measure success of the fitness module once implemented.)

- **Clicks on the fitness card:** Users that clicked on the fitness card to explore it. Will help us measure conversion of those who actually started their fitness journey
- **Daily Active Users (DAU) on Fitness:** How many users engage with the fitness module daily. We aim to increase this as the module offers daily content.
- **Workout Completion Rate:** What percentage of started workouts are completed. A high completion rate indicates the workouts are well-tailored and the experience is smooth.
- **Retention & Stickiness:** 7-day or 30-day retention of users who engage with fitness. If the personalized and engagement features work, we should see more users coming

back regularly (as supported by gamification theory).

- **Average Workouts per Week per User:** Are users exercising more consistently after using the app? Our goal is to form a habit (at least 3 workouts per week on average, growing over time).

- **Cross-Module Adoption:** How many fitness users adopt nutrition plans and vice versa, due to the upsell cards. If the integration works, there should be a lift in multi-module usage.

- **User Satisfaction:** Through app store reviews, and possibly an in-app survey, gather qualitative feedback on the fitness module. Key question: “Does the fitness module help you stay active and fit?” We want high positive responses.

- **AI Chatbot Usage:** Number of AI tip taps and questions asked. Are users finding value in the chatbot? A high engagement here means users trust the app for advice.

- **Program Completion Rate:** What fraction of users who start a program finish it. Higher is better (indicates content is doable and motivating; if low, we adjust difficulty or length).

- **Conversion/Upgrade (if relevant later):** While we’re not focusing on free vs premium now, in the future if premium content is added, we’d measure upgrade rate influenced by the fitness module’s value.

By monitoring these, the product team can iterate on the module (e.g., if we see drop-offs at week 2 of programs, maybe the content is too hard or not varied enough; if chatbot usage is low, perhaps it needs better surfacing or users don’t know what to ask).

Conclusion: The Fitness Module is a feature-rich component of the Women’s Health App that will provide a comprehensive and personalized fitness journey for our users. By leveraging personal health data, AI-driven insights, and proven engagement techniques, it aims to stand out from generic fitness apps. All the features described – from dynamic daily workouts to multi-week programs, real-time coaching, and cross-module integration – are designed to support women in staying active in a way that aligns with their bodies and lifestyles.

This PRD lays out the detailed functionality and user experience expected.. With careful execution, the fitness module will significantly enhance the value of our app and help our users achieve healthier lives in a supportive, intelligent way.

Additions to address design details and some queries

Fitness Onboarding Inputs

On the onboarding screens where we ask about equipment (home or gym) and workout intensity (beginner, intermediate, advanced), these inputs can be skippable and do not need to be mandatory. The daily workout recommendation logic does not need to depend on these factors, and they should not block the user from proceeding.

Workout Recommendation Algorithm & LLM Cost Optimization

The AI team is required to propose an optimized approach for generating daily workout recommendations. If cost optimization requires research, this research should be included as part of their deliverables.

The team must clearly define:

- Whether a tag-based logic approach is viable.
- Whether long-term fine-tuning on the knowledge base is possible to avoid repeatedly processing the entire knowledge base.
- The complete algorithmic plan for generating workout recommendations.

The final output should include a scalable and cost-efficient logic for workout generation.

Dashboard Structure & Alerts

The main dashboard should display mixed tips across fitness, nutrition, and other modules.

The fitness internal dashboard should display only fitness-related tips and should not include mixed module labels.

Fitness-specific alerts should not be shown separately within each module. All alerts should remain centralized on the main dashboard to avoid overwhelming the user. Fitness-only users will still have access to the main dashboard, so they can still see alerts.

Exercise Classification & Knowledge Base

All exercises must be categorized as either time-based or set-based. A corresponding classification column will be added to the knowledge database by Product, which will be used to determine which exercises will have timers vs. reps.

Calorie Recommendation Logic

A formula will be created based on BMI and relevant ranges to recommend calorie counts. This formula will be defined at the product level and implemented in the backend so calorie targets can be dynamically adjusted based on user inputs.

Daily Workout Plan Generation

When a user enters the fitness module, seven days of workouts will be generated upfront based on the user's goal and relevant inputs.

Users can:

- View workouts up to seven days in advance.
- Navigate back to previous days.
- See completion status (completed, partially completed, not completed).

All AI-generated workout plans and recommendations must be stored in the backend per user.

Workout Execution Flow

When the user clicks "Start Workout," they will be taken to a list of exercises generated by AI.

The AI determines:

- The type of exercises.
- The number of exercises.
- The structure based on the user's goal.

The total workout duration will be calculated based on individual exercise durations and displayed along with thumbnails on the main workout card.

Health Checker & Fitness Alerts

A fitness health checker must be included within the module.

Fitness-related alerts are supported, but alerts will remain centralized on the main dashboard rather than being duplicated across modules.

Daily Habit Exercise

A single daily habit exercise will be provided as a fallback option in case the user does not want to complete the full workout.

This exercise:

- Will be associated with the user's goal.
- Can be handled via backend rule-based logic.
- Can be linked to the user's cycle phase or date where relevant.

Workout Plan Regeneration Logic

The entire workout plan will be regenerated if the user updates key inputs such as:

- Wellness goal
- Current weight
- Other core profile data

Settings Structure

There will be a shared general settings section common to both Nutrition and Fitness where users can update:

- Age
- Weight
- Height
- Overall wellness goal

In addition, each module will have module-specific settings.

If the user updates module-specific inputs such as:

- Allergies (Nutrition)
- Workout goal
- Body focus area

The respective workout or meal plan must update accordingly.

Fitness MVP PRD - Version 1.1 (March 27, 2026)

This revision proposes some modifications to the current PRD. The elements not mentioned in this section will remain unchanged and will be handled according to the original PRD.

What the fitness module is trying to do

The fitness module is meant to feel like a guided fitness companion, not a static workout library and not an endless stream of random AI-generated workouts. The user should always feel like there is a clear path in front of her, that the app understands her goal and current state, and that she does not need to think too hard about what to do next. The system should reduce decision-making, create a visible sense of progression, adapt to the user's real-life behavior, and keep giving her enough reward and guidance that she wants to come back the next day.

The core principle is that the user should not feel like she is choosing from many disconnected fitness options. Instead, she should feel like she is entering a structured journey that becomes more personalized as she uses it.

How the user first enters the fitness module

After onboarding, the fitness module should show the user a small number of recommended programs at the top. Each recommended program should clearly communicate:

- what the program helps her achieve
- how long it runs for
- what kind of effort is required
- what style of workouts she can expect
- who the program is suitable for

The copy should feel supportive and trainer-like rather than technical. The point is to help her trust the program and feel that it is relevant to her.

At the same time, the user should not be blocked if she is not ready to commit to a program immediately. So below the program recommendations, there should also be a lighter entry point where she can experience immediate value without making a big decision. This could be shown as a "Start today's workout" or "Try a quick workout" option.

This part is important because many users will hesitate before committing to a program, especially if they are new to working out, not sure if they can keep up, or just browsing. The app should let them experience the quality of the module immediately while still making it clear that the fuller and more effective path is through a program.

The screen should also gently guide users toward commitment using copy such as:

- “You’ll make faster progress if you follow a program. Start one to track your daily progress.”

- “Unlock the full power of your plan. Join a program to reach your goal faster and track your daily progress.”

If the user taps this CTA, she should be taken into program exploration.

What happens if the user does not start a program

This is a very important edge case because a large number of users will not start a program immediately. If the user scrolls through the recommended programs, reads them, maybe taps into one or two, but exits without starting anything, the app should not simply bring her back to the same passive state next time.

When she comes back to the fitness module in her next session, the system should respond more actively. One recommended program should be surfaced more strongly rather than showing equal emphasis on all options. The quick workout option should still be available so that there is a low-friction way to take action immediately.

The point of this state is not to force commitment. It is to reduce hesitation. The user should feel that there is always an easy starting point, but also a stronger guided path if she wants faster or more measurable progress.

If the user keeps doing quick workouts but avoids joining a program, the app should begin nudging her after one or two sessions with copy like:

- “You’ve started building a routine. Join a program to track your progress and reach your goal faster.”

- “Unlock the full power of your plan. Join a program to reach your goal faster and track your daily progress.”

This should create a natural bridge from casual engagement into structured commitment.

What the program details page should show

When the user opens a program, she should not see a giant static list of exact exercises for four weeks. That would either overwhelm her or lock the product into something too rigid that later becomes difficult to personalize. At the same time, the user does need enough clarity to trust the program and feel comfortable starting it.

So the program details page should show the overall shape of the journey, not a rigid day-by-day list of exact exercises.

The user should see:

- what the program is designed to help her achieve by the end of the set duration
- how many weeks it lasts
- how much time she should expect to spend on a typical day
- what kind of workout focus each stage of the program has
- one sample workout or sample day so she knows what the actual exercise experience might feel like

This page should also explain clearly that the exact daily workout will be generated in a personalized way within the structure of the program. In other words, the program gives the journey and progression, while the app adapts the exact workout each day based on her activity, how she is feeling, and any signals from her wider persona.

This allows the app to build trust without creating a false expectation that every single day's exact workout is locked forever.

How the program should work once the user starts it

Once the user starts a program, that program should become her primary state inside fitness. She should not continue to bounce between multiple unconnected pathways. The fitness module should now feel focused.

When she comes into the module, she should see:

- the name of the program she is currently enrolled in
- where she is in the journey, such as Day 3 of 28

- a progress indicator that helps her understand she is moving through something meaningful
- one primary action, which is to start today's workout

This is important because the user should not have to decide every day what type of workout to do. The program should do that work for her.

How the daily workout is generated inside the program

When the user taps "Start workout," the app should generate that day's workout within the structure of the program she has joined.

The key idea here is that the program provides a stable and trustworthy structure, while the exact exercises inside each day are adapted based on the user's reality.

So the daily generation should work like this:

- the program determines what kind of day this is supposed to be, such as lower body, mobility, cardio, recovery, or core
- the system then selects the exact exercises that fit that day's structure
- those exercises are filtered and adapted based on the user's goal, past activity, behavior, current life stage, and relevant constraints

For example, if the user is on a lower body day but has logged back pain or has shown signs of low energy, the system should not abandon the lower body day entirely. Instead, it should keep the structure of the day and swap in safer or lower-impact exercises within that category. This is where the app feels highly personalized without becoming random.

The user should see:

- the full set of exercises for today
- animations for each exercise
- instructions
- total duration of the workout
- enough context to feel that this plan was made for her

The wording should reinforce adaptation in a simple way, such as:

- “Your workout for today has been adapted based on your recent activity and how you’re feeling.”
- “Today’s workout fits your current pace and progress.”

What happens if the user doesn’t feel like doing the full workout

A major retention risk in fitness products is the all-or-nothing feeling. If the user feels like the only option is to complete a full workout, she is more likely to skip entirely. So the product should always include a fallback path that still keeps the habit alive.

At any point before or during the workout, the user should be able to choose a lighter alternative with language like:

- “Don’t feel like doing the full workout? Try a quick version.”
- “Want something lighter today? We can shorten this for you.”

This fallback should not feel like failure. It should feel like a smart and valid alternative.

This matters because the long-term goal is not just exercise completion. It is habit formation. A user who does a short lighter workout consistently is much more valuable than a user who repeatedly skips because the default feels too hard.

How the app should handle skipped workouts

When the user misses a day and then comes back, the system should not pretend nothing happened and it should definitely not punish her. It should acknowledge the missed day in a calm and understanding way.

For example, when she returns, the app can show:

- “Missed yesterday. What happened?”
- “Looks like yesterday didn’t work out. Want to adjust today’s plan?”

The response options should be very simple:

- Too tired
- Too busy
- Didn’t feel like it
- Workout was too hard

These options matter because they help the app understand not just that she skipped, but why she skipped.

Then the system should adjust accordingly:

- if she was too tired, the next workout should be shorter and lower in intensity
- if the workout was too hard, the difficulty should be stepped down
- if she was too busy, the next workout should prioritize a compact, high-value version
- if she simply didn’t feel like it, the system can continue the same progression but perhaps with a lighter entry prompt

If she doesn’t answer the question at all, the app should still infer from her behavior and make modest adjustments rather than acting like everything is fine.

This is how the app starts to feel like a trainer who is paying attention.

How progress should be shown

The user needs to feel that her actions are adding up to something. A progress bar alone is not enough unless the user understands what that progress means.

So the app should show:

- how many days or sessions of the program she has completed
- how far she has come in the current week
- what milestone she has reached
- occasional motivational messages that connect effort to progress

Examples:

- “Week 1 complete. You’ve started building consistency.”
- “You’ve completed 3 workouts this week. Keep going.”
- “You’re building momentum.”

The progress signals should make the journey feel real and worth continuing.

What happens when a user finishes the workout for the day

At the end of each workout, the app should not simply show a completion state and stop. It should close the loop for today and set up the next day.

The user should leave that session with:

- a feeling of achievement
- a sense that her progress moved forward
- a reason to return tomorrow

Possible messages:

- “Today’s workout is complete. Your next step is ready tomorrow.”
- “Nice work. Come back tomorrow to keep your streak going.”
- “You’re moving forward. Tomorrow’s workout will continue the plan.”

The user should always know that the journey is continuing.

How the System Evaluates User Progress in Fitness

The fitness module continuously evaluates the user’s behavior over a rolling 7-day window to determine whether she is progressing effectively toward her goal or whether the system needs to adapt.

This evaluation is based on three core behavioral signals:

- percentage of workouts completed
- frequency of skipped sessions
- frequency of reduced-intensity or incomplete workouts

Based on these signals, the system classifies the user into one of three states.

On Track (High Consistency State)

The user is considered to be on track when she is completing most of her recommended workouts and engaging with the program as expected.

Definition:

- **70 percent or more of workouts completed over the last 7 days**
- no more than 1 skipped session
- minimal use of fallback/light workouts
- no repeated mid-workout drop-offs

System behavior:

- continue current progression
- gradually increase intensity if appropriate
- maintain structure of the program

Messaging:

- “You’re on track. Keep going.”
- “Nice consistency. We’re gradually increasing your intensity.”

Building Consistency (Adaptive State)

The user enters this state when she is still engaging but showing signs that the current plan may be slightly too demanding or inconsistent for her current lifestyle or energy level.

Definition:

- **40 to 70 percent of workouts completed over the last 7 days**

  OR

- **1 to 2 skipped sessions within 7 days**

  OR

- **2 to 3 uses of fallback/light workouts**

  OR

- **1 to 2 mid-workout exits**

System behavior:

- reduce workout duration slightly
- reduce intensity
- simplify exercise selection
- increase likelihood of successful completion

Messaging (first occurrence):

- “We’ve adjusted your plan to make it easier to stay consistent.”

Messaging (if pattern continues for 2–3 sessions):

- “You’re building a routine. Consistency matters more than intensity right now.”
- “Staying consistent with lighter workouts will still move you forward.”

Slow Progress (At-Risk State)

The user enters this state when her current behavior pattern strongly indicates that progress toward her goal will be slower unless consistency improves.

This does not mean failure. It means the system needs to actively guide expectations and rebuild momentum.

Definition:

- **less than 40 percent of workouts completed over the last 7 days**

  OR

- **3 or more skipped sessions within 7 days**

  OR

- **3 or more fallback/light workouts within 7 days**

  OR

- **2 or more repeated mid-workout exits across sessions**

System behavior:

- significantly reduce workout intensity and duration
- prioritize easy wins and completion
- avoid introducing additional difficulty
- maintain program continuity

Messaging:

- “You’ve been taking it slower recently. If you want to reach your goal faster, we can gradually increase intensity when you’re ready.”

Supporting reinforcement:

- “At your current pace, progress will be steady but slower.”

How the System Decides When to Transition Between States

The system does not react to a single session. It evaluates behavior across a **rolling 7-day window** to avoid overreacting to temporary fluctuations.

Transition logic:

- If the user drops below **70 percent completion**, she moves out of On Track
- If the user drops below **40 percent completion**, she moves into Slow Progress
- If the user improves to **70 percent or more completion again**, she returns to On Track

This ensures that:

- the system feels stable and predictable
- small fluctuations do not cause sudden changes
- meaningful patterns drive adaptation

How Intensity Recovers After a Slow Phase

When the user begins to recover from a slow or inconsistent phase, the system should not immediately jump back to full intensity. Instead, it should detect consistent improvement and then gradually increase difficulty.

Recovery trigger:

- **3 consecutive full workout completions**
- no fallback usage
- no mid-workout exits

System behavior:

- slightly increase intensity

- increase workout complexity or duration gradually

Messaging:

- “Nice consistency. We’re gradually increasing your intensity.”

This ensures that:

- recovery feels earned
- intensity increases feel natural
- the user is not overwhelmed again

How the System Prevents Artificial or Fake Completion

The system should not reward single-session completion. Instead, it should look for patterns across multiple sessions.

Intensity increases and progression should only occur when:

- completion is sustained over multiple days
- fallback usage is low
- the user consistently finishes workouts

This ensures that:

- users are not incentivized to tap through workouts
- progression reflects actual engagement
- trust in the system is maintained

How Progress Expectations Are Managed Without Timelines

Since the system does not show fixed timelines in the MVP, it needs to manage user expectations through behavior-based feedback rather than dates.

When the user is consistent, the system reinforces forward movement.

When the user is inconsistent, the system subtly communicates the tradeoff between pace and progress without introducing pressure.

The key principle is:

- never promise outcomes tied to time
- always reflect outcomes tied to behavior

This keeps the system honest, adaptable, and aligned with real user behavior.

What happens if the user only uses the lighter or fallback workouts

This is an edge case because some users may enjoy the module but avoid the main program path. This should be allowed initially, but if it continues, the app should gently educate the user that she will reach her goal faster through the program.

After one or two fallback sessions, the app can reinforce:

- “You’ll make faster progress if you follow a program.”
- “Join a program to reach your goal faster and track your daily progress.”

This should not feel like scolding. It should simply remind the user that there is a stronger path available.

What happens if the user changes her goal midway

This is another critical edge case. If the user updates her wellness goal from settings, it is not right to abruptly inactivate or erase the current program. That would feel jarring and disrespect the effort already invested.

Instead, the app should:

- keep the current program visible as something she had been working on

- surface new recommended programs based on the updated goal
- clearly tell her that these new programs are better aligned with what she wants now

For example:

- “Your goal has changed. Here are programs better suited to your new goal.”

The user can then choose whether to:

- continue with the current program
- or switch to one of the newly recommended programs

If she switches, the new program becomes the primary one and the old one remains visible as incomplete or archived rather than disappearing entirely.

What happens when the program is completed

Program completion should feel like a milestone, not just another screen state. The user should feel recognized and guided into the next chapter.

When the user completes the final day of the program, she should see:

- a clear completion message
- a short summary of what she has accomplished
- a clear next step

Possible next steps could include:

- moving into a more advanced program
- repeating the same goal at a higher level
- switching goals
- or re-evaluating progress and making adjustments

The app should not let the user finish and then wonder what to do now.

The review that happens after program completion (Optional for MVP)

At the end of a 4-week program, the app should run a short review rather than assuming the goal is now complete. One four-week program rarely “finishes” a goal like weight loss, muscle gain, or improved stamina. The app should treat this moment as a check-in and adjustment point.

The review should be tied to the user’s goal and should ask questions that actually make sense for that goal.

For weight loss or weight-related goals, questions could include:

- “Have you noticed any change in your weight?”
- “How do your clothes feel?”
- “Would you like to log your current weight?”

For strength-related goals:

- “Do your workouts feel easier than before?”
- “Do you feel stronger in your day-to-day movement?”

For stamina:

- “Do you feel less tired or more energetic during the day?”
- “Do longer workouts feel more manageable now?”

For flexibility or mobility:

- “Do you feel more comfortable in your movement?”
- “Has stiffness reduced?”

These responses should not just be shown and ignored. They should become part of the next recommendation cycle.

How the app should interpret the end-of-program review

At this stage, the app should combine:

- the user's consistency during the program
- her program completion data
- her self-reported review answers
- and any supporting data from other modules if available

This should not become a freeform AI diagnosis in the MVP. That would be too risky and unpredictable. Instead, the MVP should use structured questions and controlled interpretation.

Two example outcomes:

If the user had low consistency:

- "We noticed you missed around 40 percent of sessions. Let's try a lighter version of this program first to build the habit."

If the user had high consistency but reports low visible progress:

- "Your body might be plateauing. Let's adjust your plan."
- This could lead to a suggestion such as changing workout intensity or nudging the user toward a nutrition adjustment

This is where cross-module upselling could also be done.

How fitness-only users should be handled

Fitness-only sign-up is valid and should be supported because it widens the top of the funnel and allows people to enter based on movement goals alone.

But the app should still gently incentivize the wider ecosystem when relevant.

For example, if a fitness-only user repeatedly logs low energy or struggles to complete workouts, the app can surface something like:

- “We noticed your energy is dipping. Sync your Period Module to see if this is hormonal and get a tailored recovery plan.”

This should feel like helpful context, not forced upsell.

Edge Cases

The user lands on Fitness and does nothing

If the user opens the fitness module, sees the recommended programs, but neither starts a program nor tries a workout, the system should not leave her in the same passive state forever. The next time she comes back, one strong recommendation should be highlighted more prominently and the quick-start workout should be easier to spot. The app should gently reduce choice overload and make the next action more obvious.

The user keeps exploring programs but never commits

If the user opens several programs, reads them, but never starts one, that usually means she does not yet trust what she is committing to. The app should reduce uncertainty by showing one sample day, expected time commitment, and effort level more clearly. The goal is to help her feel that she understands enough to begin.

The user starts a program but never starts the first workout

If the user taps start program and then leaves before beginning the workout, the next session should take her directly back into that program state with her first day and a clear Start Workout CTA. She should not have to browse all over again.

The user starts a workout and exits midway once

One early drop-off should not trigger a big redesign. The next session should simply check in lightly, ask what happened, and adapt modestly.

The user repeatedly exits midway through workouts

Repeated drop-off is a stronger sign that the system is asking too much. The app should actively shorten and simplify the next session, and use supportive language that makes the adjustment visible as explained above.

The user skips a day and comes back

Skipping a single day is normal. The app should continue the journey calmly and offer a reset into today's workout without making the user feel behind.

The user skips multiple days in a row

If the user disappears for several days, the app should not bring her straight back into the same difficulty. It should ease her back in with a lighter entry point and a tone that reduces guilt.

The user only does quick workouts for many sessions

This is still useful behavior because it keeps the habit alive. But the app should gradually reinforce that a program will help her make more visible progress.

The user finishes the program but doesn't feel results

In that case, the app should not just congratulate her and move on. It should actively diagnose whether the issue is poor consistency, mismatch in workout structure, or missing support from other modules like nutrition.

The user completes workouts easily and quickly

This should be read as a signal that she may be ready for a greater challenge. The system can then gradually increase difficulty or progression rather than letting the program feel stagnant.

The user changes her goal in the middle of a program

The app should preserve continuity by keeping her old program visible while recommending a better one for the new goal. This respects her history and gives her a clear path forward.

The user's selected goal is not safe or appropriate for her current state

If the user is in a restricted life stage, the system should not offer unsuitable programs. Instead, it should redirect her to safe and relevant alternatives with a supportive explanation.

Role of AI Across the Journey

Where AI is involved when the user first enters fitness

AI helps determine which programs are most relevant based on:

- the user's wellness goal
- life stage
- key profile and behavior signals

The expected output is not a giant list. It is a small set of recommendations that feel clearly relevant.

Where AI is involved in daily workout generation

AI does not create daily workouts from scratch in an unconstrained way. It works inside a structured program template.

Its job here is to:

- select the right exercise variants for the day's focus
- scale intensity and difficulty
- account for relevant user signals

For example:

- if the user is meant to do lower body today but has logged back pain, the system can replace higher-risk movements with safer alternatives
- if the user has been highly inconsistent, the AI can reduce the difficulty of the day's plan

The expected output is a workout that still feels like part of the program but is better suited to the user's current reality.

Where AI is involved when the user skips or struggles

AI can help interpret repeat behavior patterns such as:

- repeated skipping
- repeated drop-off midway
- sudden decline in completion

In the MVP, the direct adjustment should remain largely rule-based so that behavior is predictable and easy to control. AI can support pattern recognition in the background, but the actual response logic should be simple and safe.

Where AI is involved at the end of the program

The user's post-program review should become an input into the next step. However, in the MVP, the questions themselves should be product-defined and goal-specific rather than dynamically generated. This ensures quality and relevance.

The interpretation of answers should also remain mostly structured in the MVP. For example:

- low consistency plus low results should route toward habit-building recommendations
- high consistency plus low results can route toward plan adjustment or nutrition support

AI can assist by synthesizing the user's completion data and responses into a summary, but full open-ended plateau diagnosis should not be part of the MVP. Plateauing is too complex to diagnose reliably without stronger data foundations.

What should be asked at the end of a program

The best practice for the MVP is not to ask one generic question to everyone. The question set should depend on the wellness goal.

For example:

- weight goal users should be asked about weight change and physical feel

- stamina users should be asked about tiredness and endurance
- flexibility users should be asked about movement comfort
- strength users should be asked about ease and capability

The product should control these question sets so the outputs remain reliable.

For MVP, plateau-related outputs should be based on:

- consistency thresholds
- progress data
- structured self-report responses

This should result in controlled recommendations like:

- try a lighter habit-first version
- increase difficulty slightly
- connect nutrition to support the goal

As the product matures and more longitudinal data becomes available, AI can play a larger role in diagnosing patterns more intelligently.

What AI should feel like to the user

The user should not feel like she is dealing with a mysterious machine that keeps changing things randomly. AI should feel like a quiet layer of intelligence that:

- notices
- adapts
- and makes the journey smoother

The visible output should always feel stable, relevant, and understandable.
